Description

This invention is directed to the discovery that certain peptide fragments of the prehormone, pro-glucagon, possess hormonal activities and can be used to stimulate the synthesis and secretion of the hormone, insulin. These peptide fragments are useful in therapy for the disease Diabetes mellitus.

Description of the Background Art

S. Mojsos, *The Journal of Biological Chemistry*, 361(5): 11880-11889 (5th September 1986) refers to investigations of prepro glucagon gene expression in the pancreas and intestine.

S K George *et al*, *FEBS Letters*, 192(2): 275-278 (November 1985) refers to the encoding of the human prepro glucagon gene for GLP-1 and GLP-2.

C Patzelt and E Schiltz, *Proc. Natl. Acad. Sci. U.S.A.*, 81: 5007-5011 (August 1984) refers to the major proglucagon fragment (MPGF) that contains two glucagon-related sequences.

The endocrine secretions of the pancreatic islets are under complex control not only by blood-borne metabolites (glucose, amino acids, catecholeamines, etc.), but also by local paracrine influences. The major pancreatic islet hormones (glucagon, insulin and somatostatin) interact amongst their specific cell types (A, B, and D cells, respectively) to modulate secretory responses mediated by the metabolites. Although insulin secretion is predominantly controlled by blood levels of glucose, glucagon and somatostatin stimulate and inhibit glucose-mediated insulin secretory responses, respectively. In addition to the proposed interislet paracrine regulation of insulin secretion, there is evidence to support the existence of insulinotropic factors in the intestine. This concept originates from the observations that glucose taken orally is a much more potent stimulant of insulin secretion than is a comparable amount of glucose given intravenously.

The human hormone, glucagon, is a 29-amino acid peptide hormone produced in the A-cells of the pancreas. The hormone belongs to a multi-gene family of structurally related peptides that include secretin, gastric inhibitory peptide, vasoactive intestinal peptide and glicentin. These peptides variously regulate carbohydrate metabolism, gastrointestinal mobility and secretory processing. The principal recognized actions of pancreatic glucagon, however, are to promote glycogenolysis and gluconeogenesis, resulting in an elevation of blood sugar levels. In this regard, the actions of glucagon are counterregulatory to those of insulin and may contribute to the hyperglycemia that accompanies Diabetes mellitus (Lund, P. K. *et al.*, *Proc. Natl. Acad. Sci., USA*, 79: 345-349 (1982)).

Glucagon has been found to be capable of binding to specific receptors which lie on the surface of insulin producing cells. Glucagon, when bound to these receptors, stimulates the rapid synthesis of cAMP, by these cells. cAMP, in turn, has been found to stimulate insulin expression (Korman, L.Y. *et al.*, *Diabetes*, 34:717-722 (1985)). Insulin acts to inhibit glucagon synthesis (*Review of Medical Physiology*, Ganong, W.F., 1979 Lange Publications, Los Altos, California (p. 273)). Thus the expression of glucagon is carefully regulated by insulin, and ultimately by the serum glucose level.

The glucagon gene is initially translated from a 630 base pair precursor to form the polypeptide, preproglucagon (Lund *et al.* (1982)). This polypeptide is subsequently processed to form proglucagon. Patzelt, C. *et al.*, *Nature*, 282: 260-266 (1979), demonstrated that proglucagon was subsequently cleaved into glucagon and a second polypeptide. Subsequent work by Lund, P.K. *et al.*, *supra*, Lopez L.C. *et al.*, (*Proc. Natl. Acad. Sci. USA* 80:5485-5489 (1983)), and Bell, G.I. *et al.*, (*Nature*) 302:716-718 (1983) demonstrated that the pro-glucagon molecule was cleaved immediately after lysine-arginine dipeptide residues. Studies of proglucagon produced by channel catfish (*Ictalurus punctatus*) indicated that glucagon from this animal was also proteolytically cleaved after adjacent lysine-arginine and arginine-arginine dipeptide residues (Andrews, P.C. *et al.*, *J. Biol. Chem.*, 260: 3910-3914 (1985)). Lopez, L.C. *et al.*, *supra*, and Bell, G. I. *et al.*, discovered the mammalian proglucagon was cleaved at lysine-arginine or arginine-arginine dipeptides, and demonstrated that the proglucagon molecule contained three discreet and highly homologous peptide molecules which were designated glucagon, glucagon-like protein 1 (GLP-1) and glucagon-like protein 2 (GLP-2). Lopez *et al.* concluded that glucagon-like protein 1 was 37 amino acid residues long and that glucagon-like peptide 2 was 34 amino acid residues long. Analogous studies on the structure of rat preproglucagon revealed a similar pattern of proteolytic cleavage between adjacent lysine-arginine or arginine-arginine dipeptide residues, resulting in the formation of glucagon, GLP-1 and GLP-2 (Heinrich, G. *et al.*, *Endocrinol.*, 115: 2176-2181 (1984)). Human rat, bovine, and hamster sequences of GLP-1 have been found to be identical (Ghiglione, M. *et al.*, *Diabetologia*, 27:599-600 (1984)).

The conclusion reached by Lopez *et al.* regarding the size of GLP-1 was confirmed by the work of Uttenenthal, L.O. *et al.* (*J. Clin. Endocrinol. Metabol.*, 61: 472-479 (1985)). Uttenenthal *et al.* examined the molecular forms of GLP-1 which were present in the human pancreas. Their research shows that GLP-1 and GLP-2 are present in the pancreas as 37 amino acid and 34 amino acid peptides, respectively.

The similarity between GLP-1 and glucagon suggested to early investigators that GLP-1 might have biological activity. Although some investigators found that GLP-1 could induce rat brain cells to synthesize cAMP (Hoosein, N. M. *et al.*, *Febs Lett.* 178:83-86 (1984)), other investigators failed to identify any physiological role for GLP-1 (Lopez,

L. C. *et al. supra*). The failure to identify any physiological role for GLP-I caused some investigators to question whether GLP-1 was in fact a hormone and whether the relatedness between glucagon and GLP-1 might be artifactual (Ghiglione, M. *et al. supra*).

Thus, in conclusion, the prior art reveals an awareness of the processing of a glucagon hormone precursor into a set of peptides sharing extensive homology. It has been widely assumed by those of skill in the art that these highly related glucagon-like peptides would have a biological activity. Nevertheless, extensive investigations designed to elucidate the biological effects of these molecules had been unsuccessful, except for the insulintropic activity of synthetic des-Gly³⁷ GLP-1 amide disclosed in the work by Schmidt *et al.*, *Diabetologia* 28 : 704-707 (1985).

The hormone glucagon is known to be synthesized as a high molecular weight precursor molecule which is subsequently proteolytically cleaved into three peptides: glucagon, glucagon-like peptide 1 (GLP-1) and glucagon-like peptide 2 (GLP-2). GLP-1 has 37 amino acids in its unprocessed form. This invention discloses that the unprocessed GLP-1 is naturally converted to a 31 amino acid long peptide (7-37 peptide) having amino acids 7-37 of GLP-1. This processing occurs in the pancreas and the intestine. The 7-37 peptide is an insulintropic hormone which had not previously been described. The hormone's activity appears to be specific for the pancreatic beta cells where it appears to induce the biosynthesis of insulin. The unprocessed GLP-1 peptide is essentially unable to mediate the induction of insulin biosynthesis. The insulintropic hormone is useful in the study of the pathogenesis of maturity onset diabetes mellitus, a condition in which the dynamics of insulin secretion are abnormal. Moreover, the insulintropic hormone is useful in therapy for this disease.

Thus the invention relates to a peptide comprising the sequence:

His-Ala-Glu-Gly-Thr-Phe-Thr-Ser-Asp-
Val-Ser-Ser-Tyr-Leu-Glu-Gly-Gln-Ala-
Ala-Lys-Glu-Phe-Ile-Ala-Trp-Leu-Val-
Lys-Gly-Arg-Gly

the peptide being substantially free of natural contaminants and having insulintropic activity.

It also encompasses a peptide having the formula:

(1)

wherein R¹ represents OH, OM or -NR²R³;

where M is a pharmaceutically acceptable cation or a lower branched or unbranched alkyl group;

each of R² and R³ are the same or different and independently represent a hydrogen atom or a lower branched or unbranched alkyl group; and

X is a peptide according to claim 1; or

(2) an acid addition salt thereof.

Such peptides can be used in medicine, as an insulintropic agent or in the preparation of such an agent. In the drawings:

Figure 1 shows the DNA structure and corresponding amino acid sequence of human, rat and hamster preproglucagons. The preproglucagon precursor is proteolytically cleaved at sites indicated by circles.

Figure 2 shows the effect of GLP-1 peptides on insulin mRNA levels in rat insulinoma cells.

Figure 3 shows the effects of GLP-1 peptides on angiotensinogen mRNA levels in rat insulinoma cells.

Figure 4 shows the effects of GLP-1 peptides on actin mRNA levels in rat insulinoma cells.

Figure 5 shows the effect of GLP-1 (1-37) on prolactin mRNA levels in GH4 cells.

Figure 6 shows the effects of GLP-1 (1-37) on ACTH mRNA levels in AtT-20 cells.

Peptide moieties (fragments) chosen from the determined amino acid sequence of human GLP-1 constitute the starting point in the development comprising the present invention. The amino acid sequence for GLP-1 has been reported by several researchers (Lopez, L.C. *et al* (1983) *supra*; Bell, G.I. *et al.*, (*Nature*) 302:716-718 (1983); Heinrich, G. *et al* (1984) *supra*; Ghiglione, M. *et al* (1984) *supra*). The structure of the preproglucagon gene and its corresponding amino acid sequence is shown in Figure 1. This figure further displays the proteolytic processing of the precursor gene product into glucagon and the two glucagon-like peptides. As used herein, the notation GLP-1 (1-37) refers to a GLP-1 polypeptide having all amino acids from 1 (N-terminus) through 37 (C-terminus). Similarly, GLP-1 (7-37) refers to a GLP-1 polypeptide having all amino acids from 7 (N-terminus) through 37 (C-terminus).

In one embodiment, the peptides are synthesized by the well-known solid phase peptide synthesis described by Merrifield, J. M., Chem. Soc., 85: 2149 (1962), and Stewart and Young, Solid Phase Peptide Synthesis (Freeman, San Francisco, 1969), pages 27-66, which are incorporated by reference herein. However, it is also possible to obtain fragments of the proglucagon polypeptide or of GLP-1 by fragmenting the naturally-occurring amino acid sequence, using, for example, a proteolytic enzyme. Further, it is possible to obtain the desired fragments of the proglucagon peptide or of GLP-1 through the use of recombinant DNA technology, as disclosed by Maniatis, T. et al., Molecular Biology: A Laboratory Manual, Cold Spring Harbor, NY 1982, which is hereby incorporated by reference.

The invention further pertains to a method for enhancing the expression of insulin, the method comprising providing to a mammalian pancreatic B-type islet cell an effective amount of the insulinotropic peptides disclosed above.

Included within the scope of the present invention are those amino acid sequences in the above peptides which are capable of functioning as insulinotropic hormones. A material is said to be "substantially free of natural contaminants" if it has been substantially purified from material with which it is normally and naturally found. Examples of natural contaminants with which GLP-1 (7-37) might be associated are: other peptides, carbohydrates, glycosylated peptides, lipids, membrane, etc. A material is also said to be substantially free of natural contaminants if these contaminants are substantially absent from a sample of the material.

The term "peptide" includes both synthetic and naturally-occurring amino acid sequences derivable from a naturally occurring amino acid sequence.

A peptide is said to be "derivable from a naturally-occurring amino acid sequence" if it can be obtained by fragmenting a naturally-occurring sequence, or if it can be synthesized based upon a knowledge of the sequence of the naturally occurring amino acid sequence or of the genetic material (DNA or RNA) which encodes this sequence.

An "insulinotropic activity" relates to the ability of a substance to stimulate, or cause the stimulation of, the synthesis or expression of the hormone insulin.

As is known in the art, the amino acid residues may be in their protected or unprotected form, using appropriate amino or carboxyl protecting groups. Useful cations are alkali or alkaline earth metallic cations (i.e., Na, K, Li, 1/2Ca, 1/2Ba, etc.) or amine cations (i.e., tetraalkylammonium, trialkylammonium, where alkyl can be C₁-C₁₂).

The variable length peptides may be in the form of the free amines (on the N-terminus), or acid-addition salts thereof. Common acid addition salts are hydrohalic acid salts, i.e., HBr, HI, or more preferably, HCl.

The insulinotropic property of a compound may be determined by providing that compound to animal cells, or injecting that compound into animals and monitoring the release of immunoreactive insulin (IRI) into the media or circulatory system of the animal, respectively. The presence of IRI is detected through the use of a radioimmunoassay which can specifically detect insulin. Although any radioimmunoassay capable of detecting the presence of IRI may be employed, it is preferable to use a modification of the assay method of Albano, J.D.M., et al. (Acta Endocrinol. 70: 487-509 (1972)). In this modification a phosphate/albumin buffer with a pH of 1.4 was employed. The incubation was prepared with the consecutive condition of 500 ul of phosphate buffer, 50 ul of perfusate sample or rat insulin standard in perfusate, 100 ul of anti-insulin antiserum (Wellcome Laboratories; 1:40,000 dilution), and 100 ul of [¹²⁵I] insulin, giving a total volume of 750 ul in a 10 X 75-mm disposable glass tube. After incubation for 2-3 days at 4°C, free insulin was separated from antibody-bound insulin by charcoal separation. The assay sensitivity was 1-2 uU/ml. In order to measure the release of IRI into the cell culture medium of cells grown in tissue culture, one preferably incorporates radioactive label into proinsulin. Although any radioactive label capable of labelling a polypeptide can be used, it is preferable to use ³H leucine in order to obtain labelled proinsulin. Labelling can be done for any period of time sufficient to permit the formation of a detectably labelled pool of proinsulin molecules; however, it is preferable to incubate cells in the presence of radioactive label for a 60 minute time period. Although any cell line capable of expressing insulin can be used for determining whether a compound has an insulinotropic effect, it is preferable to use rat insulinoma cells, and especially RIN - 3B rat insulinoma cells. Such cells can be grown in any suitable medium; however, it is preferable to use DME medium containing 0.1% BSA and 25 mM glucose.

The insulinotropic property of a compound may also be determined by pancreatic infusion. The in situ isolated perfused rat pancreas preparation was a modification of the method of Penhos, J. C. et al., (Diabetes, 18:733-738 (1969)). Fasted male Charles River strain albino rats, weighing 350-600 g, were anesthetized with an intraperitoneal injection of Amytal Sodium (Eli Lilly and Co.; 160 ng/kg). Renal, adrenal, gastric, and lower colonic blood vessels are ligated. The entire intestine was resected except for about four cm of duodenum and the descending colon and rectum. Therefore, only a small part of the intestine was perfused, thus minimizing possible interference by enteric substances with glucagon-like immunoreactivity. The perfusate was a modified Krebs-Ringer bicarbonate buffer with 4% dextran T70 and 0.2% bovine serum albumin (fraction V), and was bubbled with 95% O₂ and 5% CO₂. A nonpulsatile flow, 4-channel roller bearing pump (Buchler polystatic, Buchler Instruments Division, Nuclear-Chicago Corp.) was used, and a switch from one perfusate source to another was accomplished by switching a 3-way stopcock. The manner in which perfusion was performed, monitored, and analyzed followed the method of Weir, G. C. et al. (J. Clin. Investigat. 54: 1403-1412 (1974)), which is hereby incorporated by reference.

The compounds of the present invention can be formulated according to known methods to prepare pharmaceu-

tically useful compositions, whereby GLP-1 (7-37) or its functional derivatives are combined in admixture with a pharmaceutically acceptable carrier vehicle. Suitable vehicles and their formulation, inclusive of other human proteins, e. g. human serum albumin, are described for example in Remington's Pharmaceutical Sciences (16th Ed. A. Oslo Ed. Mack, Easton PA (1980)). In order to form a pharmaceutically acceptable composition suitable for effective administration, such compositions will contain an effective amount of the GLP-1 (7-37), or its functional derivatives, together with a suitable amount of carrier vehicle.

Compositions containing GLP-1 (7-37) or its functional derivatives may be administered intravenously, intramuscularly, or subcutaneously at dosages in the range of from about 1 pg/kg to 1,000 ug/kg body weight, although a lower or higher dosage may be administered. The required dosage will depend upon the severity of the condition of the patient and upon such criteria as the patient's height, weight, sex, age, and medical history.

For the purpose of parenteral administration, compositions containing GLP-1 (7-37) are dissolved in distilled water and the pH-value is adjusted to about 6 to 8. In order to facilitate the lyophilization process resulting in a suitable product, lactose could be added to the solution. The solution is then filter sterilized, introduced into vials, and lyophilized. The concentration of GLP-1 (7-37) in these compositions may vary from 10^{-12} M to 10^{-5} M.

Additional pharmaceutical methods may be employed to control the duration of action. Controlled release preparations may be achieved by the use of polymers to complex or adsorb GLP-1 (7-37) or its functional derivatives. The controlled delivery may be exercised by selecting appropriate macromolecules (for example, polyesters, polyamino acids, polyvinyl pyrrolidone, ethylenevinylacetate, methylcellulose, carboxymethylcellulose, and protamine sulfate) and the concentration of macromolecules as well as the methods of incorporation in order to control release. Another possible method to control the duration of action by controlled release preparations is to incorporate GLP-1 (7-37) into particles of a polymeric material such as polyesters, polyamino acids, hydrogels, poly (lactic acid) or ethylene vinylacetate copolymers. Alternatively, instead of incorporating GLP-1 (7-37) into these polymeric particles, it is possible to entrap GLP-1 (7-37) in microcapsules prepared, for example, by coacervation techniques or by interfacial polymerization, for example, hydroxymethylcellulose or gelatin-microcapsules and poly (methylmethacrylate) microcapsules, respectively, or in colloidal drug delivery systems, for example, liposomes, albumin microspheres, microemulsions, nanoparticles, and nanocapsules or in macroemulsions. Such teachings are disclosed in Remington's Pharmaceutical Sciences (1980).

SPECIFIC EXAMPLES

EXAMPLE 1

Rat insulinoma cells of cell line RIN-38 were derived from a continuous islet cell line, RIN-r, which was established from a transplantable rat islet cell tumor (Gazdar, A. F. et al., Proc. Nat'l Acad. Sci. U.S.A. 77: 3519-3523 (1980)). The cells were maintained in DMEM (Gibco) at a glucose concentration of 4,500 mg/L, and supplemented with 10% heat-inactivated fetal bovine serum (Gibco), 100 U/ml of penicillin and 100 ug/ml of streptomycin. Incubations were carried out at 37°C in 95% air: 5% CO₂. Cells grown in the above manner were washed and resuspended in DMEM (Gibco) containing 0.1% bovine serum albumin and 25 mM glucose. Cells were incubated with varying concentrations of GLP-1 (1-37), GLP-1 (7-37) or GLP-1 (1-36 des-gly-arg amide) for six hours, following which the effects of these agents on insulin mRNA expression were determined. Cellular RNA was analyzed for insulin specific mRNA as follows: cellular RNA was extracted from solid tumors and cells by homogenization in guanidine thiocyanate and sedimentation through a cesium chloride cushion. Poly A⁺ RNA was isolated by oligo dT cellulose chromatography (Aviv, H. et al., Proc. Nat'l Acad. Sci. U.S.A. 69: 1408-1412 (1972)). 20 ug of total RNA from each sample was fractionated by size on a 1.4% agarose gel after denaturation in glyoxal, followed by electrophoretic transfer to a nylon membrane (Nytran; Schleicher and Schuell). Blotted membranes were baked for two hours at 80°C under vacuum, prehybridized in 1M NaCl / 1% SDS / 10% Dextran sulfate at 50°C overnight and hybridized at the same temperature for 24 h after addition of the labelled probes (3-5 x 10⁵ cpm/ml); they were then washed at 55°C twice in 1 X SSC (0.15 M NaCl / 0.015M Na citrate) / 1% SDS, and exposed to X-ray film for varying times at -70°C with an intensifying screen. In all cases the concentration of peptides was 10^{-7} M.

The result of this experiment is shown in Figure 2. Lanes 1-3 (control cells), 4-6 (GLP-1 (1-37)), 7-9 GLP-1 (7-37), 10-12 (GLP-1(136 des- gly arg -amide) shows the amount of insulin specific mRNA produced. Triplicate experimental results are presented for each peptide.

Using a microdensitometer the relative amounts of insulin specific mRNA were determined. This experiment revealed that, at equal peptide concentrations, GLP-1 (7-37) stimulated insulin gene expression to more than 3 times the level found in control (untreated) cells.

EXAMPLE 2:

Rat insulinoma cells 1 cell line RIN-38 were grown in DME medium as described in Example 1. After incubation with 10^{-7} M GLP-1 (1-37, GLP-1 (7-37) and GLP-1 (1-36), the concentrations of insulin in the cell culture mediums were determined by radioimmunoassay (as described above). Insulin protein levels were determined after incubation for six hours. The results of this experiment are shown in Table 1.

TABLE 1

PEPTIDE ADDED	Insulin Produced (uUnits/ML)
None	2800
GLP-1 (1-37)	5000

EXAMPLE 3:

The pancreas of live rat was perfused with varying concentrations of GLP-1 (1-37) and GLP-1 (7-37) as described above. At one minute intervals, rat serum insulin levels in picograms/ml were determined by radioimmunoassay (as described above). The results of this experiment are shown in Table 2. Perfusions were done using peptide concentrations of 5×10^{-7} M, 5×10^{-8} M, and 5×10^{-10} M, 5×10^{-11} M and 5×10^{-12} M. Peptides were added after the zero minute serum value had been determined.

GLP-1 (1-37) was found to mediate a 3.4-fold increase in serum insulin concentrations when perfused into rat pancreas at a concentration of 5×10^{-7} M; at a concentration of 5×10^{-8} M this peptide was capable of mediating only a 2-fold increase in serum insulin levels. At a concentration of 5×10^{-10} M this peptide was found to mediate only a 20% increase in serum insulin levels.

GLP-1 (7-37) was found to be capable of stimulating a 132-fold increase in insulin levels when provided to rat pancreas at a concentration of 5×10^{-7} M. At a 10-fold lower concentration (5×10^{-8} M) this peptide was capable of directing a 21-fold increase in the serum concentration of insulin. At a concentration of 5×10^{-10} M, GLP-1 (7-37) was found to be capable of mediating an increase in serum insulin levels (32-fold). Even at a concentration of 5×10^{-11} M, GLP-1 (7-37) delivered a 15-fold increase in insulin levels whereas GLP-1 (1-37) was without effect.

This experiment shows that GLP-1 (7-37) is more than 1,000-fold more potent than GLP-1 (1-37) in stimulating insulin expression *in vivo*. In addition, the GLP-1 peptides had no effects on the release of the peptide hormones glucagon and somatostatin in these same experiments. Thus, the stimulatory effects of GLP-1 are specific for the beta cells and do not act on pancreatic alpha or delta cells.

Table 2

Insulin Produced (picograms/ml) at Peptide Concentration						
	Time (Minutes)	5×10^{-7} M	5×10^{-8} M	5×10^{-10} M	5×10^{-11} M	5×10^{-12} M
GLP-1 (7-37)	0	50	925	205	160	50
	1	6600	20,700	7400	2400	50
	2	4700	10,500	1800	1700	50
	3	1700	4,000	760	1900	98
GLP-1 (1-37)	0	1400	3,000	500	340	50
	1	4700	6,000	600	180	50
	2	2900	2,000	640	230	160
	3	2200	2,000	430	340	50

EXAMPLE 4:

In order to determine whether glucagon-like proteins were capable of affecting cellular cAMP levels the effects of GLP-1 (7-37) and GLP-1 (1-37) on cAMP levels in RINS-38 insulinoma cells was determined. Cells were grown as described in Example 1, in 26 well culture dishes. Varying amounts of glucagon-like peptides were added to culture wells in triplicate. After permitting incubation for 10 minutes the total cell media was examined for cAMP, and the concentration of cAMP was determined. The results of this experiment are shown in Table 3. 20 ul from each culture well was assayed.

Table 3

Peptide Concentration (M)	pMOLES OF cAMP PRODUCED	
	Expt I	Expt II
0	140	91
10^{-6}	400	170
10^{-7}	370	120
10^{-8}	494	160
10^{-9}	515	100
10^{-10}	253	90
10^{-11}	533	90

This experiment reveals that GLP-1 (7-37) was capable of stimulating cAMP levels even when present at a concentration of 10^{-11} M. The increase in cAMP levels is an indication that GLP-1 (7-37) is capable of interacting with cellular receptors.

EXAMPLE 5

In order to demonstrate that the effects of GLP-1 (1-37), GLP-1 (1-36) and GLP-1 (7-37) were specific for insulin, and were not capable of inducing or provoking non-specific gene expression, the effect of these peptides on the levels of actin and angiotensinogen mRNAs were conducted. RIN-38 insulinoma cells were grown as described in Example 1 and incubated in the presence of GLP-1 (1-37), GLP-1 (7-37), or GLP-1 (1-36) des-Gly arg (Peninsula Laboratories). In all cases the concentration of peptides was 10^{-7} M. Incubations were for six hours. Messenger RNAs specific for insulin, actin, or angiotensinogen were identified by Northern hybridization as described in Example 1. The results of this experiment are shown in Figure 2 (insulin mRNA); Figure 3 (angiotensinogen mRNA); and Figure 4 (actin mRNA). mRNA levels were determined in arbitrary densitometric units obtained from scanning films of the RNA gels of Figures 2, 3, and 4. The mRNA levels are shown in Table 4.

TABLE 4

EFFECTS OF GLUCAGON-LIKE PEPTIDES ON CELLULAR LEVELS OF mRNAs ENCODING INSULIN, ACTIN AND ANGIOTENSINOGEN IN RIN-38 INSULINOMA CELLS			
PEPTIDE*	MESSENGER RNAs		
	INSULIN	ACTIN	ANGIOTENSINOGEN
GLP-I (7-37)	4.23±0.74	0.82±0.08	2.78±0.46
GLP-I (1-37)	1.87±0.56	0.91±0.02	2.25±0.20
GLP-I (1-36)	2.78±0.80	0.88±0.03	2.56±0.22
des-Gly Arginineamide Control (no peptide)	1.28±0.23	0.89±0.05	2.67±0.31

EXAMPLE 6

GLP-1 (1-37) was examined to determine whether it could induce the biosynthesis of hormones other than insulin. Thus, GLP-1 (1-37) (at a concentration of 10^{-7} M) was added to a rat islet glucagon-producing cell line and two pituitary cell lines (GH4 and AtT-20) which were capable of producing the hormones prolactin and ACTH, respectively, and the amount of hormone specific mRNA produced was determined after 24 hours as described in Example 1. Prolactin mRNA levels in GH4 pituitary cells after incubation with GLP-1 peptides is shown in Figure 5. ACTH mRNA levels in AtT-20 pituitary cells after incubation with GLP-1 peptides is shown in Figure 6. These experiments revealed that GLP-1 (1-37) did not have any detectable effect upon the amount of mRNA which encodes these peptide hormones.

EXAMPLE 7

The effect of GLP-1 (7-37) on the transcription of the insulin and actin genes in RIN-38 insulinoma cells was investigated. Gene transcription rates were determined by quantification of nascent glucagon and beta-actin RNA transcripts in nuclei from control and TPA treated cells. Nuclear RNA was hybridized to an excess of cloned specific

DNA bound to nitrocellulose and the filters were washed as described by McKnight, G. S. *et al.* (*J. Biol. Chem.* 254: 9050-9058 (1979)). Rat glucagon (Heinrich, G. *et al.*, *Endocrinology*, 115: 1-6, (1984)) and, for control, chicken beta-actin cDNAs, provided by Dr. D. Cleveland, the Johns Hopkins University School of Medicine, Baltimore, Maryland, were used. Hybridization efficiency was controlled through the addition of the hybridization solution of [³H] UTP glucagon cRNA. Experiments were done in duplicate and values are expressed in ppm/kb of cDNA insert, corrected for efficiency of hybridization (40-50%). Cells were incubated with GLP-1 (7-37) at a concentration of 10⁻⁷M for 4 hours. Nuclei were prepared from cells at 0, 1 and 4 hours and nascent insulin gene and actin gene transcripts were assessed by the nuclear run on assay (McKnight, G. S. *et al.*). The results of this experiment are shown in Table 5. The experiment shows that GLP-1 (7-37) increases the rate of insulin gene transcription, but has no detectable effect upon the rate of actin gene expression.

TABLE 5

EFFECT OF GLUCAGON-LIKE PEPTIDE I (7-37) ON TRANSCRIPTION OF THE INSULIN AND ACTIN GENES IN RIN-38 INSULINOMA CELLS		
TIME (hrs)	INSULIN GENE	ACTIN GENE
0	17.4	34.1
1	76.2	29.9
4	9.0	25.0

Claims

Claims for the following Contracting States: BE, CH, DE, FR, GB, IT, LI, LU, NL, SE

1. A peptide having insulinotropic activity comprising the sequence:

His-Ala-Glu-Gly-Thr-Phe-Thr-Ser-Asp-
Val-Ser-Ser-Tyr-Leu-Glu-Gly-Gln-Ala-
Ala-Lys-Glu-Phe-Ile-Ala-Trp-Leu-Val-
Lys-Gly-Arg-Gly

but not including GLP-I (1-37).

2. A peptide having the formula:

(1)

wherein R¹ represents OH, OM or -NR²R³;

where M is a pharmaceutically acceptable cation or a lower branched or unbranched alkyl group;

each of R² and R³ are the same or different and independently represent a hydrogen atom or a lower branched or unbranched alkyl group; and

X is a peptide according to claim 1; or

(2) an acid addition salt thereof.

3. A peptide as claimed in claim 2 wherein R¹ represents -NR²R³.

4. A method of enhancing the in vitro expression of insulin, the method comprising providing to a mammalian pancreatic B-type islet cell in a medium an effective amount of an insulinotropic peptide according to any of claims 1 to 3

5. A pharmaceutical insulinotropic composition comprising an effective amount of a peptide according to any of claims 1 to 3, in association with a suitable physiologically acceptable carrier.

6. A peptide as claimed in any of claims 1 to 3 for use in the preparation of an insulinotropic agent.
7. The use of a peptide according to any of claims 1 to 3 for the manufacture of an insulinotropic agent.
8. A peptide as claimed in any of claims 1 to 3 for use in medicine.

Claims for the following Contracting State : AT

1. A process for the preparation of a peptide having insulinotropic activity comprising the sequence:

His-Ala-Glu-Gly-Thr-Phe-Thr-Ser-Asp-
Val-Ser-Ser-Tyr-Leu-Glu-Gly-Gln-Ala-
Ala-Lys-Glu-Phe-Ile-Ala-Trp-Leu-Val-
Lys-Gly-Arg-Gly

- but not including GLP-I (1-37);
the process comprising synthesizing the protein, fragmenting a naturally occurring amino acid sequence or by using DNA or RNA encoding the protein and recombinant DNA technology.

2. A process for the preparation of a peptide having the formula:

(1)

- wherein R¹ represents OH, OM or -NR²R³;
where M is a pharmaceutically acceptable cation or a lower branched or unbranched alkyl group;
each of R² and R³ are the same or different and independently represent a hydrogen atom or a lower branched or unbranched alkyl group; and
X is a peptide according to claim 1; or

- (2) an acid addition salt thereof,
the process comprising synthesizing the protein, fragmenting a naturally occurring amino acid sequence or by using DNA or RNA encoding the protein and recombinant DNA technology and where necessary forming a hydroxy, ester, salt or amino derivative thereof.

3. A peptide as claimed in claim 2 wherein R¹ represents -NR²R³.
4. A method of enhancing the in vitro expression of insulin, the method comprising providing to a mammalian pancreatic B-type islet cell an effective amount of an insulinotropic peptide according to any of claims 1 to 3.
5. A process for the formulation of a pharmaceutical insulinotropic composition the process comprising admixing an effective amount of a peptide according to any of claims 1 to 3, with a suitable physiologically acceptable carrier.
6. A peptide as claimed in any of claims 1 to 3 for use in the preparation of an insulinotropic agent.
7. The use of a peptide according to any of claims 1 to 3 for the manufacture of an insulinotropic agent.

Patentansprüche

Patentansprüche für folgende Vertragsstaaten : BE, CH, DE, FR, GB, IT, LI, LU, NL, SE

1. Peptid mit insulinotroper Aktivität, welches folgende Sequenz umfaßt:

His-Ala-Glu-Gly-Thr-Phe-Thr-Ser-Asp-
 Val-Ser-Ser-Tyr-Leu-Glu-Gly-Gln-Ala-
 Ala-Lys-Glu-Phe-Ile-Ala-Trp-Leu-Val-
 Lys-Gly-Arg-Gly

aber nicht GLP-I (1-37) enthält.

2. Peptid mit der Formel:

(1)

worin R^1 OH, OM oder $-NR^2R^3$ darstellt;

wobei M ein pharmazeutisch annehmbares Kation oder eine gering verzweigte oder nicht verzweigte Alkylgruppe ist;

wobei jedes von R^2 und R^3 gleich oder verschieden ist und unabhängig ein Wasserstoffatom oder eine gering verzweigte oder nicht verzweigte Alkylgruppe darstellt; und
 X ein Peptid nach Anspruch 1 ist; oder

(2) ein Säureadditionssalz davon.

3. Peptid nach Anspruch 2, worin $R^1 -NR^2R^3$ darstellt.

4. Verfahren zur Verstärkung der in vitro Expression von Insulin, wobei das Verfahren die Zugabe einer wirksamen Menge eines insulinotropen Peptids nach einem der Ansprüche 1 bis 3 zu einer pankreatischen B-Typus Inselzelle eines Säugetiers in einem Medium umfaßt.

5. Pharmazeutische insulinotrope Zusammensetzung, umfassend eine wirksame Menge eines Peptids nach einem der Ansprüche 1 bis 3 in Verbindung mit einem geeigneten, physiologisch annehmbaren Träger.

6. Peptid nach einem der Ansprüche 1 bis 3 zur Verwendung in der Herstellung eines insulinotropen Mittels.

7. Verwendung eines Peptids nach einem der Ansprüche 1 bis 3 für die Herstellung eines insulinotropen Mittels.

8. Peptid nach einem der Ansprüche 1 bis 3 in der Medizin.

Patentansprüche für folgenden Vertragsstaat : AT

1. Verfahren zur Herstellung eines Peptids mit insulinotroper Aktivität, welches folgende Sequenz umfaßt:

His-Ala-Glu-Gly-Thr-Phe-Thr-Ser-Asp-
 Val-Ser-Ser-Tyr-Leu-Glu-Gly-Gln-Ala-
 Ala-Lys-Glu-Phe-Ile-Ala-Trp-Leu-Val-
 Lys-Gly-Arg-Gly

aber nicht GLP-I (1-37) enthält;

wobei das Verfahren das Synthetisieren des Proteins, Fragmentieren einer natürlich vorkommenden Aminosäuresequenz oder das Kodieren des Proteins unter Verwendung von DNA oder RNA und rekombinante DNA-Technologie umfaßt.

2. Verfahren zur Herstellung eines Peptids mit der Formel:

(1)

worin R^1 OH, OM oder $-NR^2R^3$ darstellt;

wobei M ein pharmazeutisch annehmbares Kation oder eine gering verzweigte oder nicht verzweigte Alkylgruppe ist;

wobei jedes von R^2 und R^3 gleich oder verschieden ist und unabhängig ein Wasserstoffatom oder eine gering verzweigte oder nicht verzweigte Alkylgruppe darstellt; und
X ein Peptid nach Anspruch 1 ist; oder

(2) ein Säureadditionssalz davon,

wobei das Verfahren das Synthetisieren des Proteins, Fragmentieren einer natürlich vorkommenden Aminosäuresequenz oder die Kodierung des Proteins unter Verwendung von DNA oder RNA und rekombinante DNA-Technologie umfaßt und falls notwendig, die Bildung eines Hydroxy, Ester, Salz oder Aminoderivates davon.

3. Peptid nach Anspruch 2, worin R^1 $-NR^2R^3$ darstellt.

4. Verfahren zur Verstärkung der in vitro Expression von Insulin, wobei das Verfahren die Zugabe einer wirksamen Menge eines insulinotropen Peptids nach einem der Ansprüche 1 bis 3 zu einer pankreatischen B-Typus Inselzelle eines Säugetiers in einem Medium umfaßt.

5. Verfahren zur Zubereitung einer pharmazeutischen insulinotropen Zusammensetzung, wobei das Verfahren das Vermischen einer wirksamen Menge eines Peptids nach einem der Ansprüche 1 bis 3 mit einem geeigneten physiologisch annehmbaren Träger umfaßt.

6. Peptid nach einem der Ansprüche 1 bis 3 zur Verwendung in der Herstellung eines insulinotropen Mittels.

7. Verwendung eines Peptids nach einem der Ansprüche 1 bis 3 für die Herstellung eines insulinotropen Mittels.

Revendications

Revendications pour les Etats contractants suivants : BE, CH, DE, FR, GB, IT, LI, LU, NL, SE

1. Peptide ayant une activité insulinotrope comprenant la séquence :

His-Ala-Glu-Gly-Thr-Phe-Thr-Ser-Asp-Val-
Ser-Ser-Tyr-Leu-Glu-Gly-Gln-Ala-Ala-Lys-
Glu-Phe-Ile-Ala-Trp-Leu-Val-Lys-Gly-Arg-Gly

mais ne comprenant pas GLP-I (1-37).

2. Peptide de formule :

(1)

où R^1 représente OH, OM ou NR^2R^3 ;

où M est un cation pharmaceutiquement acceptable ou un radical alcoyle inférieur branché ou linéaire;
chaque R^2 et R^3 sont les mêmes ou différents et représentent indépendamment un atome d'hydrogène ou un radical alcoyle inférieur branché ou linéaire, et

X est un peptide suivant la revendication 1, ou

(2) un sel d'addition acide de celui-ci.

- 5 3. Peptide suivant la revendication 2, dans lequel R¹ représente NR²R³.
4. Procédé d'augmentation de l'expression in vitro de l'insuline, le procédé comprenant l'addition à un milieu contenant des cellules pancréatiques B de type îlot de mammifères, une quantité efficace d'un peptide insulinothéropé suivant l'une quelconque des revendications 1 à 3.
- 10 5. Composition insulinothéropé pharmaceutique comprenant une quantité efficace d'un peptide suivant l'une quelconque des revendications 1 à 3, en association avec un excipient physiologiquement acceptable.
6. Peptide suivant l'une quelconque des revendications 1 à 3, à utiliser dans la préparation d'un agent insulinothéropé.
- 15 7. Utilisation in vitro d'un peptide suivant l'une quelconque des revendications 1 à 3, pour la préparation d'un agent insulinothéropé.
8. Peptide suivant l'une quelconque des revendications 1 à 3, à utiliser en médecine.
- 20

Revendications pour l'Etat contractant suivant : AT

- 25 1. Procédé de préparation d'un peptide ayant une activité insulinothéropé comprenant la séquence :

His-Ala-Glu-Gly-Thr-Phe-Thr-Ser-Asp-Val-
Ser-Ser-Tyr-Leu-Glu-Gly-Gln-Ala-Ala-Lys-
Glu-Phe-Ile-Ala-Trp-Leu-Val-Lys-Gly-Arg-Gly

30 mais ne comprenant pas GLP-1 (1-37);

le procédé comprenant la synthèse de la protéine, la fragmentation d'une séquence d'acides aminés naturelle ou l'utilisation d'un ADN ou d'un ARN codant la protéine et la technologie de l'ADN recombiné.

- 35 2. Procédé de préparation d'un peptide de formule :

(1)

40 où R¹ représente OH, OM ou NR²R³;

où M est un cation pharmaceutiquement acceptable ou un radical alcoyle inférieur branché ou linéaire; chaque R² et R³ sont les mêmes ou différents et représentent indépendamment un atome d'hydrogène ou un radical alcoyle inférieur branché ou linéaire, et

X est un peptide suivant la revendication 1, où

(2) un sel d'addition acide de celui-ci,

le procédé comprenant la synthèse de la protéine, la fragmentation d'une séquence d'acides aminés naturelle ou l'utilisation d'un ADN ou d'un ARN codant la protéine et la technologie de l'ADN recombiné et, si nécessaire, la formation d'un dérivé hydroxyle, d'un ester, d'un sel ou d'un dérivé amino de celui-ci.

- 50 3. Peptide suivant la revendication 2, dans lequel R¹ représente NR²R³.
4. Procédé d'augmentation de l'expression in vitro de l'insuline, le procédé comprenant l'addition à des cellules pancréatiques B de type îlot de mammifères, une quantité efficace d'un peptide insulinothéropé suivant l'une quelconque des revendications 1 à 3.
- 55 5. Procédé de formulation d'une composition insulinothéropé pharmaceutique, le procédé comprenant le mélange d'une quantité efficace d'un peptide suivant l'une quelconque des revendications 1 à 3 avec un excipient physiologique-

ment acceptable approprié.

6. Peptide suivant l'une quelconque des revendications 1 à 3, à utiliser dans la préparation d'un agent insulinothérapeutique.
7. Utilisation in vitro d'un peptide suivant l'une quelconque des revendications 1 à 3, pour la préparation d'un agent insulinothérapeutique.
